

Raspbot Low battery voltage situation (Raspberry Pi 5 version)

note:

- When the battery voltage is low by 9.5V, the power light of the Raspberry Pi 5 remains red and cannot be turned on. This requires the battery to be fully charged, as shown in the picture, which means the battery is completely dead.

- When charging the battery, the charger indicator light will turn red, and when fully charged, it will turn green. After charging is completed, the charger and power should be unplugged in a

timely manner to avoid overcharging and damaging the battery. Someone needs to be present during charging.

- When the battery voltage is around 11.1V, it needs to be charged in a timely manner. When fully charged, the battery voltage is about 12.6V. Do not let the battery experience excessive consumption multiple times, which can protect the battery's lifespan.
